

a **Measured hover completion** trajectories/completion.py, updated at every physics step with post-step truth

Reaching the reference endpoint is never success by itself. The runner reports success only if every requested physics step ran and the final status has achieved = true; otherwise the command exits with code 2. A late observation cannot turn an expired deadline into success. At reset the loop requires duration_s $\geq$ motion end + dwell_time_s + $2\Delta t$, so the criterion is always reachable in time.

b

The endpoint target is reached by the reference at 11.07 s, while position, speed and yaw already satisfy their tolerances; the last one, angular speed, enters at 11.29 s, and success is latched only after 2 s of continuous compliance. Errors are clipped at 10⁻³ for display: the noise-free synthetic plant keeps converging far below the tolerances.
